Non-fermenters (also non-fermenting bacteria) are a taxonomically heterogeneous group of bacteria of the division Proteobacteria that cannot catabolize glucose, and are thus unable to ferment. This does not necessarily exclude that species can catabolize other sugars or have anaerobiosis like fermenting bacteria. The coccoid or bacillary bacteria can be found in soil or wet areas.

Because these Gram-negative bacilli survive well in many environments in nature and in homes and hospitals, they are commonly encountered in the clinical laboratory. As a group they have the following characteristics: Straight or slightly curved Gram-negative rods

Decisions about performing antimicrobial susceptibility testing are complicated by the fact that the Clinical and Laboratory Standards Institute (CLSI) interpretive guidelines for disk diffusion testing of the nonfermenting gram-negative bacteria are limited to *Pseudomonas* species, *Burkholderia cepacia*, *Stenotrophomonas maltophilia*, and *Acinetobacter* species and therefore, except for *Acinetobacter* species, do not include the organisms covered in the chapter.
