In fact, it is also possible to construct a subset of  $[0,1]$  that is meager but of positive measure and a subset that is non-meager but of measure zero: By taking the countable union of "fat" Cantor sets  $(C_n)$  of measure  $= (-) /$  (see Smith-Volterra-Cantor set below for the construction), we obtain a set  $:= \bigcup = \infty$  which has a positive measure (equal to 1) but is meager in  $[0,1]$ , since each  $(C_n)$  is nowhere dense.

Certainly; for example, the Cantor set contains the points 0,  $1/3$ ,  $25/27$ , and 1. The purpose of this article is to discuss exactly how many points there are in the Cantor set. How many points are there in the Cantor set? Each point of the Cantor set lies at the root of an infinite nested sequence of intervals. For example, consider the diagram below.

In other words, given any two elements  $a, b \in C$ , Cantor's set can be divided into two disjoint and closed neighborhoods  $A$  and  $B$ , one containing  $a$  and the other containing  $b$ . "Proof." Given say the numbers  $a$  and  $b$  from above: Neighborhood  $A$  = all elements of  $C$  whose 7th digit is 0. Neighborhood  $B$  = all elements of  $C$  whose 7th digit is 2.

### The Cantor Set and the Cantor Function - NTNU

The Cantor set is a famous set first introduced by German mathematician Georg Cantor in 1883. It is simply a subset of the interval  $[0;1]$ , but it has a number of remarkable and deep properties. We will first describe the construction and the formula of the Cantor ternary set, which is the most common modern construction, and then prove some interesting

$x = \sum_{k=1}^{\infty} a_k 3^{-k}$  where  $a_k = 0, 1, \text{ or } 2$ . Note that this decomposition is not unique since, for example,  $1/3 = \sum_{k=2}^{\infty} 2/3^k$ . Prove that  $x \in \text{Cantor set}$  if and only if  $x$  has a representation as above where every  $a_k$  is either 0 or 2.

The empty (or void, or null) set, symbolized by  $\{\}$  or  $\emptyset$ , contains no elements at all. Nonetheless, it has the status of being a set. A set  $A$  is called a subset of a set  $B$  (symbolized by  $A \subseteq B$ ) if all the members of  $A$  are also members of  $B$ . For example, any set is a subset of itself, and  $\emptyset$  is a subset of any set.

Cantor observed that two sets  $A$  and  $B$  have the same size if and only if there is a one-to-one correspondence between  $A$  and  $B$ , that is, there is a way of evenly matching the elements in  $A$  with the elements in  $B$ . In other words, Cantor noted that the sets  $A$  and  $B$  have the same size if and only if there is a bijection  $f: A \rightarrow B$ .
